Introduction

The MapleSim™ Control Design Toolbox provides the necessary control design tools to extend the plant modeling capabilities of MapleSim. Using a symbolic approach, you can design, analyze, and test control systems.

You can also use the technical documentation tools available with MapleSim to document your design decisions.

Features of this toolbox include:

- Model linearization
- Standard PID tuning techniques: Ziegler-Nichols time response, Ziegler-Nichols frequency response and Cohen-Coon
- Advanced PID tuning techniques: Dominant pole placement, pole placement in a specified region, and gain and phase margin
- State Feedback Control: Single input pole placement (Ackermann), multiple input pole placement, and LQR
- State Estimation: Single output pole placement (Ackermann), multiple output pole placement, and Kalman filter
- Access to commands in the ControlDesign and DynamicSystems packages in Maple™

Scope of Model Support

MapleSim Control Design Toolbox is a very comprehensive modeling tool where it is possible to design linear controllers for models created in MapleSim. The Control Design Toolbox linearizes systems of any complexity, including systems of DAEs of any index.

Systems that contain any type of discontinuity, including discrete transforms, switches, logic gates, relational and Boolean operations are not supported by the current release of this product.
1 Getting Started

1.1 Getting Help
In Maple, enter ?ControlDesign at a prompt in a worksheet.

1.2 Viewing MapleSim Control Design Examples
Toolbox examples are available in MapleSim.

To view an example:
- From the Help menu, select Examples > Control Design Examples, and then select the model that you want to view.

Some models include additional documents, such as Maple worksheets that show model equations or define custom components. To view an attached Maple worksheet:

1. From the main toolbar in MapleSim, click the Load a Maple Worksheet icon ( ![Icon](https://www.example.com/)).
2. Select the document from the list of attached worksheets, and click OK. The worksheet opens in Maple.

Alternatively, all attachments to a MapleSim model can be found under the Attached Files tab ( ![Icon](https://www.example.com/)). You can right-click (Control-click, for Mac) on an attachment and select View to open it in Maple (for Maple worksheets) or in the appropriate program.

1.3 Using the MapleSim Control Design Apps
The MapleSim Control Design Toolbox provides apps for linearizing MapleSim models and creating PID controllers. These Maple-based apps allow you to generate a linearized representation of your model subsystems, as well as custom components of your system controllers. Apps are found in the Apps Manager, opened by clicking Show Apps Manager ( ![Icon](https://www.example.com/)) from the main toolbar in MapleSim.

1.4 Example: DC Motor
In this example, you will generate a linearized state-space model of the models you created in MapleSim. You will then use this linearized model to create and tune a PID controller.

Generating a Linearized Model

To generate a linearized model:
1. From the Help menu, select Examples > Control Design Examples, and then select the DC Motor - Getting Started model.

2. From the main toolbar, click Show Apps Manager ( ![Icon](https://www.example.com/)), and from the Apps palette double-click on the Linearization entry under Component Creation. The Linearization app opens.
3. Using the drop-down list above the model, select the DC Motor1 subsystem.
4. Click **Load Selected Subsystem**. In the Configuration section, the fields for the **Inputs**, **Outputs**, and **Parameters** tables are populated with information specific to the subsystem.

5. In the **Configuration** section, select **Linearization Options**.

   You can now have the app automatically calculate an equilibrium point to be used as a linearization point or you can choose to have the model linearized about the initial point.

   If you specify manual values in the Initial Conditions of a component, these will be used in the Initial Configuration of the system. Alternatively, to calculate the equilibrium point automatically, select **Equilibrium Point**. Also, to enable Baumgarte stabilization during linearization of the constraint equations, select **use Baumgarte**.

6. For this example, select **Equilibrium Point**.

7. In the **Linearize** section, click **Linearize** to generate the linearized model. In the **Analysis** section, you can select and view the matrices of your linearized model (select **Basic**). Select **Mappings** to view the state, input, and output mappings.

8. Scroll to the bottom of the app and under **Create Model** in the **Component Name** field, you can enter a custom name for the linearized model, for example, **MyMotor** for this example. In the description field, you can add more information about your model.

9. Click **Create** to create the linearized state-space model. A custom component with the specified component name (for example, **MyMotor**) now appears in the **Components** palette of the **Local Components** tab of the DC Motor model in MapleSim.

### Creating a Custom Controller

**To create a custom controller:**

1. If you are not in the top level of your model, click **Return to Main** in the Navigation Toolbar.

2. Under the **Local Components** tab, the **MyMotor** custom component is found in the **Components** palette. Place the **MyMotor** custom component in the **Model Workspace**.

3. From the main toolbar, click **Show Apps Manager** and then double-click the **PID Tuning** entry under **Control Design** in the **Apps** palette. The **PID Tuning** app opens.

4. In the **Linearized Model** section of the app, select the linearized model **MyMotor** from the drop-down list.

5. In the **Controller Design** section, you can select the tuning method and controller type you want to create. For this example, design a **PID** controller using the modified Ziegler-Nichols (MZN) Time Domain tuning method:

   From the **Method** drop-down menu, select **Ziegler-Nichols Time Domain (MZN)**. From the **Controller** drop-down menu, select **PID**. If additional information is required for your control design method, the fields below these menus will be populated and you can enter the required information.

6. Click **Design Controller**.
7. Next, in the Export to MapleSim subsection, enter MyPID, and then click Export to MapleSim. A custom component generates and exports to MapleSim.

Notes:

- You can view the Modelica® code generated for the custom component in the Modelica Code Editor.

To simulate your model using the MyPID custom component:
1. Return to your MapleSim model.
2. Select the MyMotor custom component and click Disable to exclude it from the next simulation.
3. In the Local Components tab, the MyPID custom component is found in the Components palette. Place the MyPID custom component in the Model Workspace.
4. In the Library Components tab, expand the Signal Blocks → Common menu and drag the Feedback component in the Model Workspace.
5. Connect the components to your model, as shown below.

6. Click Run Simulation in the Main Toolbar to simulate your model. When the simulation is complete, the following graph appears.
You can change the parameters of your controller directly in your model in MapleSim by selecting the PID controller component and editing the parameters in the **Properties** tab.
